

Important components

- Ice sheet (grounded)
- Ice shelf (floating)
- Ice streams and glaciers
- Sea ice and icebergs
- Subglacial environment
- Snow cover
- Ice free areas and Permafrost
- Submarine landscapes

Important components to research at a polar environment are amongst others ice sheets, shelves, and streams, glaciers, sea ice, snow, but also the ice free areas, permafrost, and the bedrock below the snow and the ice, and not to forget the submarine landscapes. Antarctica is a place where we can research all these components and the interactions between them. Moreover, some of these components can only be found in Antarctica, e.g. ice sheets below sea level (see images at top). What else is so special about Antarctica? ...

Antarctica ...

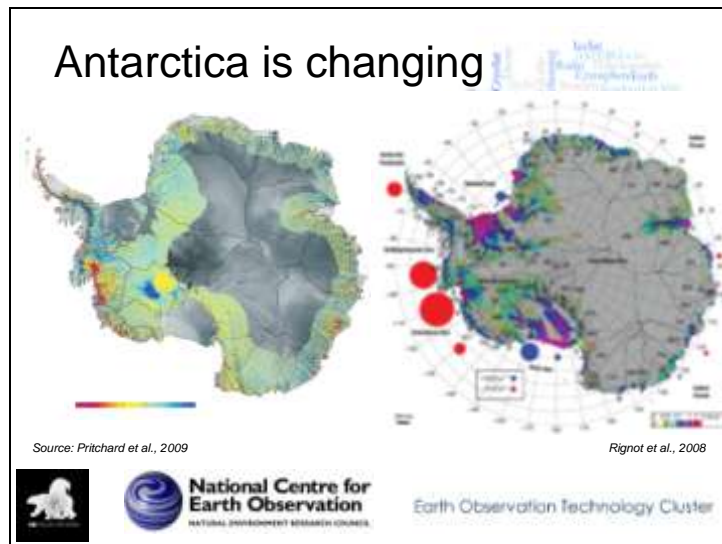

- ... is the latest discovered continent on Earth.
- ... has no inhabitants, but hosts research stations.
- ... is the coldest, driest, windiest, highest continent on Earth.
- ... is 98 % covered by ice and snow.
- ... contains 90% of Earth's ice & 70% of its freshwater.
- ... if entirely melted, the global sea level would rise by ~60m.
- ... plays an important role in the global climate system.

Satellite observations are known to provide wide/large scale information about the Earth, but also about other planets. Specially in Antarctica, with its hostile climate and remote location, satellite observations are of utmost importance. Here you can see 2 examples of products of satellite remote sensing. It demonstrates how changes of the Antarctic continent can be measured by means of different remote sensing techniques. To the left altimetry data from the icesat satellite is used to measure changes in the height of the Antarctic surface. To the right radar data is used to determine the velocity of ice streams, galciers, and ice shelves.
